The **blox** package*

Ben Reish
ben.reish@alumni.oc.edu
February 25, 2021

Abstract

The **blox** package is an English translation of the French **schemabloc** package for making block diagrams in **LATEX2e**. Also, I fixed the chain feature to auto-create a linear linked chain of blocks from a list which did not work on my implementation of **tikz** and **schemabloc**.

1 Introduction

Have you ever needed to make a block diagram for a control system like Fig. 1? Or, maybe to explain an algorithm? The **blox** package is an option to meet this need. It allows for the use of most of **tikz**’s personalization capability for the blocks themselves and the lines. But, the defaults look pretty good by themselves.

I mention the **tikz** package because this package is based on the **tikzpicture** environment. I refer you to the **pgf/tikz** documentation for specifics on using the **tikzpicture** environment. I will only show the necessities to be able to use this package.

So if **schemabloc** had not required me to repeatedly use Google® Translate to figure out what was going on, I would never have created this package. If you like French or can read it, please use the **schemabloc** package.

∗This document corresponds to **blox** v2.51, dated 2021/2/22.

1See http://ctan.org/pkg/pgf.

\bXOutput{E}{C}
\bXLink[y]{C}{E}
\bXReturn{C-E}{B}{H}
\end{tikzpicture}

Figure 1: Simple Negative Feedback Block Diagram and Code
2 Usage

The idea is to create a \texttt{tikzpicture} environment then place your block diagram commands inside it. The order is a bit weird. You must create both endpoints to a connecting line prior to making the line (see Fig. 2). So, instead of saying ‘make block, make link, make block’, you have to say ‘make block, make block, make connecting link.’ This is an effect of \texttt{tikz} not being a what-you-see-is-what-you-get graphics drawing program. It will help you to create a rought draft of your block diagram with pen and ink prior to trying to create it with this package.

\texttt{blox} is designed to be linear. It begins at an input and builds the diagram to the right of the previous item one item at a time. If multiple paths are needed, besides the normal feedback path like that shown in Fig. 1, special commands must be used to translate up or down to a new path.

This package is an extension of \texttt{tikz} so \texttt{\begin{tikzpicture}} must be used around these commands. This is just a reminder to use the correct environment. Once the diagram is created, it can be reduced in total size by adding an optional argument to the environment which uses the keyword scale, e.g.

\begin{figure}[h]
\centering
\begin{tikzpicture}
\node (A) at (0,0) {Input};
\node (B) at (2,0) {Comparator};
\node (C) at (4,0) {Block};
\node (D) at (6,0) {Output};
\node (E) at (8,0) {Return};
\draw (A) -- (B) -- (C) -- (D);
\end{tikzpicture}
\caption{This figure shows the Node names below their actual positions in order to show what’s going on during the build-up of the block diagram. Begin with an input, A, then add a comparator (I used the general one because I needed an odd setup), B. The add the link between the two and add the block, C. Now add the output, D, then links in between each, and you’re done with the first branch. The return line is added and creates its own branch (red) below the first branch, by default. The link macro creates a node in the middle of the link which is called \texttt{(first arg)}-\texttt{(second arg)}, C-D. Now create the third branch (green) by placing E. Then use the chain return macro to create two blocks and their links, f and g. Now use the special link macros to connect the first branch to the third.
\end{figure}
2.1 The A and the Ω

\begin{tikzpicture}[scale=0.5]

\XInput \langle label \rangle \{(Name)\}

\XOutput \langle distance \rangle \{(Name)\}\{\langle Preceding Node \rangle\}

\XLinkName \langle distance \rangle \{\langle Previous Node \rangle\}\{\langle Label \rangle\}

2.2 Blocks

There are several commands for making blocks in the \texttt{bloc} package. They are context sensitive, so where you use them matters. Some do multiple things.

\XBloc \langle distance \rangle \{(Name)\}\{\langle Contents \rangle\}\{\langle Previous Node \rangle\}

\XBlocL \langle distance \rangle \{(Name)\}\{\langle Contents \rangle\}\{\langle Previous Node \rangle\}

\XBlocr \langle distance \rangle \{(Name)\}\{\langle Contents \rangle\}\{\langle Previous Node \rangle\}

\XBlocrL \langle distance \rangle \{(Name)\}\{\langle Contents \rangle\}\{\langle Previous Node \rangle\}

\XInput Every diagram begins with an entry point. I called mine an input so the command is \XInput \langle label \rangle \{(Name)\}. \langle label \rangle is printed text for the entry node. This can be blank which is default, or not included in the \XInput call at all. The link between the input node and the next block will be centered vertically on the right-hand side of whatever text is given as \langle label \rangle. \langle Name \rangle is the \texttt{tikz} node name used internally. It will not be displayed. It is used to connect and things and refer to components of the diagram inside \texttt{tikz}.

\XOutput Like the input, every diagram needs a point of exit. I called mine an output so the syntax is \XOutput \langle distance \rangle \{(Name)\}\{\langle Previous Node \rangle\}. \langle distance \rangle is an optional argument whose default is 2 that specifies how many units from \langle Previous Node \rangle to place this new node. The unit in question is the \texttt{em} or \em (the width of the capital M in the current font). \langle Name \rangle is the \texttt{tikz} node name given to this new block. \langle Previous Node \rangle is the \texttt{tikz} node name of the node (block, or comparator) immediately to the left of this new block.

\XLinkName To place the label of the output at the extreme end of the block diagram, use \XLinkName \langle distance \rangle \{\langle Previous Node \rangle\}\{\langle Label \rangle\}. \langle distance \rangle is an optional argument whose default is 0.4 units above \langle Previous Node \rangle to place \langle Label \rangle. An example is shown in Fig. 8.
the left instead of the right, again for use on the feedback or return loop. The syntax is \texttt{\textbackslash bXBlocr[\langle distance\rangle\{\langle Name\rangle\{\langle Contents\rangle\{\langle Previous Node\rangle\}. The block created by this command will be placed \langle distance\rangle (the default is 2) units to the left of \langle Previous Node\rangle and then draws the connecting link between \langle Previous Node\rangle and the new block. Links will terminate on the right-hand side of the block and begin on the left-hand side.

For those of you who do not like rectangles, there is a command for creating a “block” which is more of a floating potato instead of a rectangle. The syntax is \texttt{\textbackslash bXBlocPotato[\langle distance\rangle\{\langle Name\rangle\{\langle Contents\rangle\{\langle Previous Node\rangle\}. This command makes a single floating potato outline around whatever is in \langle contents\rangle and places it to the right of \langle Previous Node\rangle by \langle distance\rangle units (the default is 2). See Fig. 3.

If you only want to have an input, a block, and an output, then this is the command for you. \texttt{\textbackslash bXonlyOneBloc[\langle distance\rangle\{\langle Input label\rangle\{\langle Block label\rangle\{\langle Output label\rangle\}. \langle distance\rangle is the length of the links in em’s. The labels, \langle Input label\rangle, \langle Block label\rangle, and \langle Output label\rangle, are the labels for the individual components. The names are taken care of by the macro assuming that you do not plan to have multiple instances of this macro in the same \texttt{tikzpicture}.

2.3 Comparators and Summations

Comparators and summing junctions are created with a couple of commands. All of them are limited to four connections so that the cardinal direction names can be used to describe them: north, south, west, east\textsuperscript{2}. There is the ability to have the signs inside the circle or outside. There are several simplified, user-level commands and one general command, e.g. Fig. 4 The package defines a couple others which are explained in the Implementation section.

\textsuperscript{2}If you need more connections than that, think about using multiple summing junctions first or use the full authority of \textsc{tikz} to create a block with the requisite number of connections.
The syntax is \texttt{\textbackslash bXComp*[(distance)]\{}\langle Name\rangle\}\{}\langle Previous Node\rangle\}. This command creates the normal feedback from below comparator \langle distance\rangle to the right of \langle Previous Node\rangle named \langle Name\rangle. Used with the star, the labels will be outside the empty circle and offset so as to not interfere with the links. Without the star, the circle is drawn with an X circumscribed in it and the labels will be within the circle. The default \langle distance\rangle is 4.

This command creates the normal input from below summing junction. The syntax is \texttt{\textbackslash bXSum[(distance)]\{}\langle Name\rangle\}\{}\langle Previous Node\rangle\}{\langle a\rangle}{\langle b\rangle}{\langle c\rangle}. The circle is drawn with an X circumscribed in it and the labels will be within the circle, only the east segment is not labeled due to there only being 6 arguments. Arguments \langle a\rangle, \langle b\rangle, and \langle c\rangle should be +’s to fulfill the name of the command, but they don’t have to be.

The comparator can have input from above. The user command to simply use the north and west segments for comparing is given by the following command: \texttt{\textbackslash bXCompa*[(distance)]\{}\langle Name\rangle\}\{}\langle Previous Node\rangle\} and the \texttt{\textbackslash bXSuma*} is analogous.

Comparators can have input from below as well. The user command to simply use the south and west segments for comparing is given by the following command: \texttt{\textbackslash bXCompb*[(distance)]\{}\langle Name\rangle\}\{}\langle Previous Node\rangle\} and the \texttt{\textbackslash bXSumb*} is analogous.

This is the most general command. All the previous ones used this command with arguments pre-defined. It takes seven arguments. The syntax is \texttt{\textbackslash bXCompSum*[(distance)]\{}\langle Name\rangle\}\{}\langle Previous Node\rangle\}{\langle n\rangle}{\langle s\rangle}{\langle w\rangle}{\langle e\rangle}. The starred version creates an empty circle with the labels outside while the non-starred version creates one where the X and the labels are within the circle. The command places the circle \langle distance\rangle to the right of \langle Previous Node\rangle named \langle Name\rangle. It places \langle n\rangle in the northern segment, \langle s\rangle in the southern segment, \langle w\rangle in the western segment, and \langle e\rangle in the eastern segment. For summing junctions, these arguments are all +’s. For comparators, one or more is a −.

2.4 Links

Connecting the blocks in a block diagram indicates the flow of information in the diagram. This is assisted by arrows on the connecting lines. I called the lines
The package expects to move from the left to the right.

The syntax is \bXLink\[⟨label⟩]\{⟨Previous Node⟩\}⟨⟨Next Node⟩⟩. The length of the line is decided by the placement of the ⟨Next Node⟩ and is not an argument of the link. This command creates an arrow from ⟨Previous Node⟩ to ⟨Next Node⟩ with the arrow tip pointing at ⟨Next Node⟩ (see Fig. 1 for r, u, or y) and ⟨label⟩ above the middle of the link. The default label is blank.

The command \bXLinkxy uses the same arguments. It creates a line which exits from the east side of ⟨Previous Node⟩, makes a right angle and tries to connect to the north or south side of ⟨Next Node⟩. It will place the ⟨label⟩ along the vertical segment.

\bXLinktyx uses the same arguments. It creates a link which goes vertically, makes a right angle, and then goes horizontally. It has no label.

To create a feedback loop where there is measurement noise, use \bXLinkyx, then create the noise block with \bXBlocr, and then use \bXLinkxy to finish the feedback loop. If no noise is in the measurement, then use a return.

\bXLinktb draws a link from the top, center of ⟨Previous Node⟩ to the bottom, center connecting node on ⟨Next Node⟩ in a straight line. Neither macro accounts for creating a label. If a label is required, use \bXBranchy, or \bXBranchx and \bXLinkName.

\bXChain and \bXChainReturn are expected to create a set of linear blocks and links. The syntax for their used is \bXChain[(distance)]{(Previous Node)}{(Next Node)}{(list)} and \bXChainReturn[(distance)]{(Previous Node)}{(Next Node)}{(list)}. ⟨distance⟩ is the number of em's separation between blocks in the chain. The default is 4. ⟨Previous Node⟩ is the starting node for the chain. ⟨list⟩ is a list of pairs of names and labels of the form: name/label,name2/label2,... as in Fig. 5. The \bXChainReturn
Figure 5: Example of a Chain and Code

\begin{tikzpicture}

\end{tikzpicture}

\textbf{2.7 Specialty Items}

This section discusses the additional macros that don’t fit into the previous categories.

\textbf{2.7.1 New Branches}

When you have a highly complex block diagram to create like Fig. 8 or Fig. 2, this package requires you to make new branches by telling it where in relation to an existing node to begin the new branch. You may move horizontally or vertically from an existing node. In Fig. 8, there are two \texttt{\textbackslash xReturn}'s used which take care of placing the new branch internally. But, the upper row with the System block is the item of interest. In Fig. 2, the branches are noted by color: black for the first branch, red for the second, and green for the third.

\textcolor{red}{\textbackslash XBranchx}
\textcolor{green}{\textbackslash XNodeShiftx}
\textcolor{blue}{\textbackslash XBranchy}
\textcolor{blue}{\textbackslash XNodeShifty}

The macro to create a new \texttt{tikz} node at some horizontal distance is given by

\begin{verbatim}
\texttt{\textbackslash \textbackslash XBranchx}\texttt{\{distance\}\{\texttt{Previous Node}\}\{\texttt{Name}\}. \texttt{(distance)} is an optional argument whose default is 5 that specifies how many units to the right of \texttt{Previous Node} to place this new node. \texttt{(Name)} is the \texttt{tikz} name for the node. You will use \texttt{(Name)} for the \texttt{Previous Node} of the first new block on this branch. I think the horizontal shift will be used rarely. \texttt{\textbackslash XNodeShiftx} is the obsolete version of this command with the same arguments. This macro is only retained for version compatibility.
\end{verbatim}

\texttt{\textbackslash \textbackslash XBranchy}
\texttt{\textbackslash XNodeShifty}

The macro to create a new \texttt{tikz} node vertically displaced is given by

\textcolor{red}{\texttt{\textbackslash \textbackslash XBranchx}}
\textcolor{green}{\texttt{\textbackslash XNodeShiftx}}

\textcolor{blue}{\texttt{\textbackslash \textbackslash XBranchy}}
\textcolor{blue}{\texttt{\textbackslash XNodeShifty}}

\textsuperscript{3}There is something incorrect about the spacing on the Input label in this command
\begin{tikzpicture}
\node at (0,0) [circle, draw, minimum size=1cm] (C) {$C_3(s)$};
\node at (1,0) [circle, draw, minimum size=1cm] (P2) {$P_2(s)$};
\node at (2,0) [circle, draw, minimum size=1cm] (P3) {$P_3(s)$};
\node at (-1,0) [xanchor=south] {$C_2(s)$};
\node at (-2,0) [xanchor=south] {$C_1(s)$};
\draw[->] (C) -- node[above]{$u_3$} (P3);
\draw[->] (P2) -- node[above]{$y_2$} (P3);
\draw[->] (C) -- node[above]{$u_2$} (P2);
\draw[->] (P2) -- node[left]{$u_1$} (C);
\draw[->] (P3) -- node[above]{$y_1$} (P2);
\draw[->] (P3) -- node[above]{$y_2$} (P2);
\draw[->] (P3) -- node[above]{$y_3$} (P2);
\end{tikzpicture}

Figure 7: Customized Block Diagram and Code
Figure 8: A Multi-Input, Branched Example and Code
\texttt{\textbackslash BRanchy[\langle distance\rangle]}\{(\texttt{Previous Node})\}\{\langle Name\rangle\}. \langle distance\rangle is an optional argument whose default is 5 that specifies how many units below \langle Previous Node \rangle to place this new node. \langle Name \rangle is the \texttt{tikz} name for the node. You will use \langle Name \rangle for the \langle Previous Node \rangle of the first new block on this branch. \texttt{\textbackslash Nodeshifty} is the obsolete version of this command with the same arguments. This macro is only retained for version compatibility. See Fig. 8.

2.7.2 Personalization

Since this package is built on \texttt{tikz}, the full authority of the \texttt{tikz} environment is available for personalizing the look of your block diagram.

\texttt{\textbackslash Defaul霆LineStyle} The default line style is stored in \texttt{\textbackslash Defaul霆LineStyle}. If you change the line style, using \texttt{\textbackslash LineStyle} then the default can be reapplied by using \texttt{\textbackslash Defaul霆LineStyle}. The default line style is a solid black, thin line with \LaTeX{} style arrow tips.

\texttt{\textbackslash LineStyle} To change the default, use \texttt{\textbackslash LineStyle\{\langle Style list\rangle\}}. \langle Style list\rangle is a comma separated list of \texttt{tikz} keywords to change the display of the line. See Fig. 7 for an example. Refer to the \texttt{pgf/tikz} Manual for a complete listing of available keywords.

\texttt{\textbackslash StyleBlocDefault} The default block style is stored in \texttt{\textbackslash StyleBlocDefault} and can be used to restore the default settings if they are changed. The default style is a 3em square, outlined with a thin black line.

\texttt{\textbackslash StyleBloc} To change the default, use \texttt{\textbackslash StyleBloc\{\langle Style list\rangle\}}. \langle Style list\rangle is a comma separated list of \texttt{tikz} keywords to change the display of the block. See Fig. 7 for an example. Refer to the \texttt{pgf/tikz} Manual for a complete listing of available keywords.

\texttt{\textbackslash StyleSumDefault} The default Sum style is stored in \texttt{\textbackslash StyleSumDefault} and can be used to restore the default settings if they are changed. The default style is a circle outlined with a thin black line. The default takes the elements of the block style as a starting point.

\texttt{\textbackslash StyleSum} To change the default, use \texttt{\textbackslash StyleSum\{\langle Style list\rangle\}}. \langle Style list\rangle is a comma separated list of \texttt{tikz} keywords to change the display of the block. Refer to the \texttt{pgf/tikz} Manual for a complete listing of available keywords.

\texttt{\textbackslash DefaultLabelStyle} The default line style is stored in \texttt{\textbackslash DefaultLabelStyle}. If you change the line style, using \texttt{\textbackslash LabelStyle} then the default can be reapplied by using \texttt{\textbackslash DefaultLabelStyle}. The default line style is a solid black, thin line with \LaTeX{} style arrow tips.

\texttt{\textbackslash LabelStyle} To change the default, use \texttt{\textbackslash LabelStyle\{\langle Style list\rangle\}}. \langle Style list\rangle is a comma separated list of \texttt{tikz} keywords to change the display of the line. See Fig. 7 for an example. Refer to the \texttt{pgf/tikz} Manual for a complete listing of available keywords.

2.7.3 Scaling

There are some scaling commands that are built into \texttt{tikz}, I think. They are \texttt{tiny}, \texttt{small}, \texttt{Large} environments. The \texttt{tiny} environment decreases the font size to about 5pt and scales everything else down equivalently. The \texttt{small} environment decreases the
font size to about 8pt. The Large environment decreases the font size to about 12pt. Fig. 9 shows the same block diagram with these three environments used and a normal one for reference.

3 Tips

- If you want to work in the opposite direction than the normal one, use a negative \langle distance \rangle. This can be useful when working with returns or branches.
- If you want text under a link, you can use \bXLinkName macro with a negative \langle distance \rangle and a \langle Previous Node \rangle of the form D=E.
- It is always a good idea to draw the block diagram by hand first. Then your code for this package, simple though it is, will be neater and easier to read because you can create the diagram in order.
- When something really special is needed, do not forget that you may use tikz commands directly in your \tikzpicture environment. This is how I place...
the little filled-in blocks with the node names in Fig. 2.

4 Implementation

Here is the listing of the source code for the package. Most things here are as similar to the schemabloc package as I could make them. These macros group sets of \tikz commands together to utilize the power of \tikz but allowing the user to not have to dig into \pgf/tikz.

Normal beginning package commands to provide for making sure the package works correctly:

\typeout{*}
\typeout{blox: Just an English translation of schemabloc package.}
\typeout{blox Copyright (C) 2014-2021 Ben Reish}
\typeout{*}
\typeout{This program comes with ABSOLUTELY NO WARRANTY.}
\typeout{This is free software, and you are welcome to redistribute it}
\typeout{under certain conditions.}
\typeout{*}

The package has external dependencies beyond the base installation. I am sorry.

\RequirePackage{ifthen}
\RequirePackage{tikz}
\RequirePackage{pgffor}
\usetikzlibrary{shapes,arrows}

Using the \tikz commands, initialize the styles for links, blocks, potatoes, and summing junctions.

\tikzstyle{bXLineStyle}=[->,>=latex',
\tikzstyle{bXStyleBloc}=[draw, rectangle,
\tikzstyle{bXStyleBlocPotato}=[]
\tikzstyle{bXStyleSum}=[draw, circle,]%style Sum CC
\tikzstyle{bXLabelStyle}=[]

\bXDefaultLineStyle
\bXLineStyle

\bXDefaultLineStyle is used to re-establish the default line style once it has been changed by the below commands. It defines a solid line with a \LaTEX style arrow tip. To change the default line style, \bXLineStyle takes one argument which is added to the default line description by \tikz.

\newcommand{\bXDefaultLineStyle}{
\tikzstyle{bXLineStyle}=[->,>=latex']
}
\newcommand{\bXLineStyle}[1]{
\tikzstyle{bXLineStyle}=[#1]
}

\bXStyleBloc
\bXStyleBlocDefault

To re-establish the block style, use \bXStyleBlocDefault. To change the default, the \bXStyleBloc command will take an argument and add it to the current block style definition.
To re-establish the potato block style, use `\bXStylePotatoDefault`. To change the default, the `\bXStylePotato` command will take an argument and add it to the current block style definition.

To re-establish the block style, use `\bXStyleSumDefault`. To change the default, the `\bXStyleSum` command will take an argument and add it to the current sum style definition.

To re-establish the label style, use `\bXLabelStyleDefault`. To change the default, the `\bXLabelStyle` command will take an argument and add it to the current label style definition. This is used with the `\bXInput` and the `\bXLinkName` macros to customize the text.

I redefined the beginning command of the block diagram to take an optional argument and place it as a label above the node. This required splitting the `\bXInput` command into three commands. The user level command is `\bXInput` which looks to see if the next character is a `[`. If so, it calls `\bXInputi`, else it calls `\bXInputii`. If the optional argument is used, the `\bXInputi` command takes the list of arguments and processes them. The `\bXBranchx` is called to create the extra node labels for connecting links.
To end the block diagram with an arrow pointing to the right, place a node at the right of the previous node to which a link can connect.

\newcommand{\bXOutput}[3][2]{
\node [coordinate, right of=#3right, node distance=#1em, minimum size=0em,right] (#2) {};
\node (#2right) at (#2.east){};
\node (Blocrightend) at (#2.east){};
}

\newcommand{\bXBloc}{
\node [draw, rectangle, minimum height=3em, minimum width=3em, right of = #4right, node distance=#1em,bXStyleBloc,right] (#2) {#3};
\node (#2right) at (#2.east){};
\node (Blocrightend) at (#2.east){};
\draw [bXLineStyle,auto] (#4) -- node[#4-#2] {} (#2);
}

\newcommand{\bXBlocr}{
\node [draw, rectangle, minimum height=3em, minimum width=3em, left of = #4left, node distance=#1em,bXStyleBloc,left] (#2) {#3};
\node (#2left) at (#2.west){};
\node (Blocleftend) at (#2.west){};
}

\newcommand{\bXBlocL}{
\node [draw, rectangle, minimum height=3em, minimum width=3em, right of = #4right, node distance=#1em,bXStyleBloc,right] (#2) {#3};
\node (#2right) at (#2.east){};
\node (Blocrightend) at (#2.east){};
\draw [bXLineStyle,auto] (#4) -- node[name=#4-#2] {} (#2);
}

\newcommand{\bXBlocrL}{
\node [draw, rectangle, minimum height=3em, minimum width=3em, left of = #4left, node distance=#1em,bXStyleBloc,left] (#2) {#3};
\node (#2left) at (#2.west){};
\node (Blocleftend) at (#2.west){};
}
\texttt{\textbackslash XBlocPotato} This command gives the user an option for a nondescript object by using \texttt{tikz}'s built in \texttt{cloud} keyword.

\begin{verbatim}
\newcommand{\bXBlocPotato}[4][2]{
  \node [draw, cloud, cloud puffs=5, draw, minimum height=3em, minimum width=5em, right of = #4right, node distance=#1em,bXStyleBlocPotato,right] (#2) {#3};
  \node (#2right) at (#2.east){};
}
\end{verbatim}

\texttt{\textbackslash XOnlyOneBloc} This macro creates an entire single block, block diagram by itself. It adds an input, a block, an output, and two links with the four arguments being the labels for everything.

\begin{verbatim}
\newcommand{\bXonlyOneBloc}[4][1.5]{
  \bXInput{E1}
  \bXBloc[#1]{B1}{#3}{E1}
  \bXOutput[#1]{S1}{B1}
  \bXLink{E1}{B1}{#2}
  \bXLink{B1}{S1}{#4}
}
\end{verbatim}

\texttt{\textbackslash XLink} These macros tell \texttt{tikz} where to place links, between which blocks. The normal macro is \texttt{\bXLink} which takes 3 arguments. It draws straight lines between the right edge of the previous node and the left edge of the next node. It names the link \texttt{(Previous Node)-(Next Node)}. This allows the selection of the middle of the link between to blocks for the having a return link drawn from. This macro will draw diagonal lines between nodes on different branches of a diagram. To maintain square corners, use the \texttt{\bXLinkxy} to go first horizontally, then vertically; or use \texttt{\bXLinkyx} to go first vertically and then horizontally. To link from the top of the first block to the next block horizontally, use \texttt{\bXLinktyx} and to link from the top of the first block to the bottom of the second block, use \texttt{\bXLinktb}.

\begin{verbatim}
\newcommand{\bXLink}[3][{}]{
  \draw [bXLineStyle,auto] (#3) -- node[name=#3-#2] {#1} (#2);
}
\end{verbatim}

This macro draws a right-angled line between two nodes, the top of the first argument and the east or west side of the second argument. \texttt{tikz} will try to connect to the closest node. There is no label making option.
This macro draws a straight line between two nodes, the top of the first argument and the bottom of the second argument. It can be a diagonal line. There is no label making option.

\newcommand{\bXReturn}[4][]{
\node [below of=#2, node distance=#1em, minimum size=0em](return#2) {};
\draw [bLineStyle] (#2.south)--(return#2.south)
-| node[near end,right] {#4} (#3) ;
}

\bXReturn This macro creates two nodes, one directly below the second argument and one directly below the third argument. Then it draws straight lines to connect them.

\newcommand{\bXCompSum}{\@ifstar{\bXCompSumNorm}{\bXCompSumOnly}}
\newcommand{\bXCompSumNorm}[7][]{
\node [draw, circle,minimum size=2em, right of=#3,node distance=#1em] (#2) {};
\node [draw, cross out,minimum size=1.414em, right of=#3,node distance=#1em] {};
\node [above of=#2,node distance=0.6em] {$#4$};
\node [below of=#2,node distance=0.6em] {$#5$};
\node [left of=#2,node distance=0.6em] {$#6$};
\node [right of=#2,node distance=0.6em] {$#7$};
\node (#2right) at (#2.east){};
\node (#2left) at (#2.west){};
}\newcommand{\bXCompSumOnly}[7][]{
\node [draw, circle,minimum size=2em, right of=#3,node distance=#1em] (#2) {};
\node [draw, cross out,minimum size=1.414em, right of=#3,node distance=#1em] {};
\node [above of=#2,node distance=0.6em] {$#4$};
\node [below of=#2,node distance=0.6em] {$#5$};
\node [left of=#2,node distance=0.6em] {$#6$};
\node [right of=#2,node distance=0.6em] {$#7$};
\node (#2right) at (#2.east){};

}
In an effort to reduce the keystrokes needed to produce a comparator, \texttt{\bXComp} is offered. It is broken into three macros to take care of whether or not the user wants an ‘X’. These macros just hardcode some inputs to the \texttt{\bXCompSum} macro.

\begin{verbatim}
\newcommand*{\bXComp}{\@ifstar{\bX@CompNorm}{\bX@CompOnly}}
\newcommand{\bX@CompOnly}[3][4]{\bXCompSum[#1]{#2}{#3}{}{-}{+}{}}
\newcommand{\bX@CompNorm}[3][4]{\bXCompSum*[#1]{#2}{#3}{}{-}{+}{}}
\end{verbatim}

Again, in an effort to reduce keystrokes, a macro is offered to make a comparator whose negative input is from above. It, too, is split into three macros to handle the starred version.

\begin{verbatim}
\newcommand*{\bXCompa}{\@ifstar{\bX@CompaNorm}{\bX@CompaOnly}}
\newcommand{\bX@CompaOnly}[3][4]{\bXCompSum[#1]{#2}{#3}{-}{}{+}{}}
\newcommand{\bX@CompaNorm}[3][4]{\bXCompSum*[#1]{#2}{#3}{-}{}{+}{}}
\end{verbatim}

To meet the same need as that of \texttt{\bXCompa}, but with a summing junction, \texttt{\bXSuma} is offered.

\begin{verbatim}
\newcommand*{\bXSuma}{\@ifstar{\bX@SumaNorm}{\bX@SumaOnly}}
\newcommand{\bX@SumaOnly}[3][4]{\bXCompSum[#1]{#2}{#3}{+}{}{+}{}}
\newcommand{\bX@SumaNorm}[3][4]{\bXCompSum*[#1]{#2}{#3}{+}{}{+}{}}
\end{verbatim}

To meet the same need as that of \texttt{\bXComp}, but with a summing junction, \texttt{\bXSumb} is offered.

\begin{verbatim}
\newcommand*{\bXSumb}{\@ifstar{\bX@SumbNorm}{\bX@SumbOnly}}
\newcommand{\bX@SumbOnly}[3][4]{\bXCompSum[#1]{#2}{#3}{}{+}{+}{}}
\newcommand{\bX@SumbNorm}[3][4]{\bXCompSum*[#1]{#2}{#3}{}{+}{+}{}}
\end{verbatim}
\bXSum I think this macro is for printing out an empty comparator or summing junction with few keystrokes. I think it is redundant, but here it is.
\newcommand{\bXSum}{\node [draw, circle, minimum size=1.5em, right of=#3, node distance=#1em, label=175:\$#4\$, label=-85:\$#5\$, label=85:\$#6\$, \bXStyleSum] (#2) {}}; 
\node (#2right) at (#2.east){}; 
\node (#2left) at (#2.west){};
}

\bXBranchy The \bXBranchy macro is used to create a node vertically displaced from the third argument by the first argument. This allows for multiple inputs and outputs in a block diagram. It creates the node names right and left for other macros to use. The \bXNodeShifty macro is retained for version compatibility.
\newcommand{\bXBranchy}{\node [below of=#2, node distance=#1em, minimum size=0em](#3) {};} 
\node (#3right) at (#3){}; 
\node (#3left) at (#3){}; 
}
\newcommand{\bXNodeShifty}{\bXBranchy[#1]{#2}{#3} }

\bXBranchx The \bXBranchx macro is used to create a node horizontally displaced from the third argument by the first argument. It creates the node names right and left for other macros to use. The \bXNodeShiftx macro is retained for version compatibility.
\newcommand{\bXBranchx}{\node [right of=#2, node distance=#1em, minimum size=0em](#3) {};} 
\node (#3right) at (#3){}; 
\node (#3left) at (#3){}; 
}
\newcommand{\bXNodeShiftx}{\bXBranchx[#1]{#2}{#3} }

\bXChain A chain is a set of blocks connected to each other created from a list. This function leans heavily on the \texttt{tikz foreach} command. There are a couple of special versions of this command which were previously (in \texttt{schemabloc}) used together unsuccessfully. I don’t think \texttt{tikz} allows the combination of its versions of the \texttt{foreach} command. I simplified the use to be a selection from a list of comma-separated values of the form: a/b, c/d, . . . which was useful to me. I then used a global let statement to redefine what \texttt{\lastx} was each iteration. This seems to work. The \texttt{typeout} is for debugging. I like the lists so I left it un-commented.
\newcommand{\bXChain}{\node [draw, circle, minimum size=1.5em, right of=#3, node distance=#1em, label=175:\$#4\$, label=-85:\$#5\$, label=85:\$#6\$, \bXStyleSum] (#2) {}}; 
\node (#2right) at (#2.east){}; 
\node (#2left) at (#2.west){};
}
\def\lastx{#2} \%  
\foreach \x / \y in {#3} {  
\{\bXBlocL[#1]{\x}{\y}{\lastx} \%  
\typeout{\x, \y, \lastx} \%  
\global\let\lastx\x}  
}  
\bXChainReturn  
This macro has the same machinations that the previous one does, but is to be
used on the return side, so the block command is swapped out with \bXBlocrL.
Otherwise, it works just as the \bXChain macro does.
\newcommand{\bXChainReturn}[3][4] {  
\def\lastx{#2} \%  
\foreach \x / \y in {#3} {  
\{\bXBlocrL[#1]{\x}{\y}{\lastx} \%  
\typeout{\x, \y, \lastx} \%  
\global\let\lastx\x}  
}\bXOnlyLoop  
This command is supposed to create a block diagram for you, but it errors out so
I have removed it from this version of the \texttt{blox} package. \texttt{tikz} can not find a node
that it is looking for and I haven't figured that one out yet.
\newcommand{\bXOnlyLoop}[4][4] {  
\bXComp[#1]{Comp#2}{#2} \bXLink{#2}{Comp#2}  
\bXChain[#1]{Comp#2}{#3}  
\draw [bXLineStyle, auto] (Blocrightend.base) --++(1em,0)coordinate [name=EndofChain];  
\bXReturn{EndofChain}{Comp#2}{#4}  
}\bXLoop  
This macro is designed to make a loop diagram from a list of values. You make
an input and then hand this macro a \texttt{\langle distance\rangle}, the name of your input, and a
list like: \texttt{a/$G_1$,b/$G_2$}. It just draws a line from the end of the list of block
back to the comparator.
\newcommand{\bXLoop}[3][4] {  
\bXComp[#1]{Comp#2}{#2} \bXLink{#2}{Comp#2}  
\bXChain[#1]{Comp#2}{#3}  
\draw [bXLineStyle, auto,-] (Blocrightend.base) --++(1em,0)coordinate [name=EndofChain];  
\bXReturn{EndofChain}{Comp#2}{#4}  
}\bXLoopReturn  
This is the same idea as the previous macro, but adds a second list argument
which allows for a set of blocks to be set on the return loop as well. It, too, does
not work properly, so I have commented it out of this version.
\newcommand{\bXLoopReturn}[4][4] {  
\bXComp[#1]{Comp#2}{#2} \bXLink{#2}{Comp#2}  
\bXChain[#1]{Comp#2}{#3}  
}\pagebreak
Change History

v1.0
  General: Initial version ............ 1

v2.0
  \bXChain: Simplified the foreach statement from tikz and applied a global let statement 18
  General: Fixed the chain mechanism to work with my implementation of tikz ............ 1

v2.1
  General: Converted the input command to actually display whatever text is put in the optional argument ............ 3

v2.2
  \bXOnlyLoop: Removed the \bXOnlyLoop macro and \bXLoopReturn macro for further study. ............ 19
  General: Added Branchx and Branchy macros and made \bXNodeShiftx/y obsolete ............ 7

v2.3
  \bXStylePotatoDefault: Added the style commands for the potato which were missing. .. 13

v2.4
  \bXComp: Converted \bXCompNorm and \bXCompOnly to private functions. ............ 17
  \bXCompSum: Converted \bXCompSumNorm and \bXCompSumOnly to private functions. ............ 16

v2.5
  \bXSuma: Converted \bXSumaNorm and \bXSumaOnly to private functions. ............ 17
  \bXSumb: Converted \bXSumbNorm and \bXSumbOnly to private functions. ............ 17
  General: Added discussion of the \bXLabelStyle and \bXDefaultLabelStyle macros. . 10
  General: Changed the name to \texttt{blox} instead of \texttt{bloX} at CTAN's suggestion. ............ 1

v2.51
  \bXLinktb: Added \bXLinktyx and \bXLinktb to be able to link blocks from the top of the starting block ............ 15
  General: Added description of \bXLinktyx and \bXLinktb macros. ............ 6
