1 Documentation

The etl package provides a few slow but expandable alternatives to unexpandable functions found inside the \l3tl module of expl3. All user functions must not contain the tokens \s__etl_stop or \__etl_act_result:n in any argument unless specified otherwise (there might be other forbidden tokens, all of which are internals to this package, and usually shouldn’t somehow end up inside the input stream by accident).
There is another limitation of this package: There are tokens which cannot expandably be differentiated from each other, those are active characters let to the same character with a different category code, something like the following:

\char_set_catcode_letter:N a
\char_set_active_eq:NN a a
\char_set_catcode_active:N a

After this the active ‘a’s couldn’t be told apart from non-active ‘a’s of category letter by the parsers in this package. In general two tokens are considered equal if \etl_token_if_eq:NNTTF yields true (see there). Another limitation is that the parser doesn’t consider the character code of tokens with category 1 or 2 (group begin and group end, typically { }), instead all tokens found with these two category codes are normalised to {{1} and {2}}.

The core macro \etl_act:nnnnnn is modelled after an internal of l3tl called \_\_tl_act:NNNn but with some more possibilities added.

1.1 A general loop

\etl_act:nnnnnnn ⋆ \etl_act:nnnnnn ⋆ \etl_act:nnnnn ⋆ \etl_act_output:n {⟨token list⟩} ⋆
\etl_act:nnnnn ⋆ \etl_act:nnnnn ⋆ {⟨normal⟩} {⟨space⟩} {⟨group⟩} {⟨final⟩} {⟨status⟩} {⟨output⟩}
\etl_act:nnnnn ⋆ {⟨token list⟩}
\etl_act:nnnnn ⋆ {⟨normal⟩} {⟨space⟩} {⟨group⟩} {⟨final⟩} {⟨status⟩} {⟨token list⟩}
\etl_act:nnnnn ⋆ {⟨token list⟩}

This function will act on the ⟨token list⟩ (somewhat a map_tokens-function). Both ⟨normal⟩ and ⟨group⟩ should be code that expects two following arguments (the first being the ⟨status⟩, the second the next N-type token or the contents of the next group in the ⟨token list⟩), and ⟨space⟩ should expect only the ⟨status⟩ as a following argument.

You can also specify ⟨final⟩ code which will receive the ⟨status⟩ followed by the output (which you can assign with \etl_act_output:n and \etl_act_output_pre:n), and will be used inside an e-expansion context (so you’ll want to protect anything you want to output from further expansion using \exp_not:n). Also you can specify some ⟨output⟩ which should be there from the beginning.

Functions without the argument ⟨output⟩ will start with an empty output, and those without ⟨final⟩ will just output the results at the end.

T_{\text{E}}Xhackers note: The result is returned within \exp_not:n, which means that the token list does not expand further when appearing in an x- or e-type argument expansion. The result will be returned after exactly two steps of expansion. If you don’t need the ⟨final⟩ argument processor and don’t have to reorder some of the output you can also use \exp_not:n to directly output tokens where you currently are, this might be faster.

\etl_act_output:n ⋆ \etl_act_output:n ⋆ \etl_act_output_pre:n ⋆
\etl_act:nnnnn ⋆ \etl_act:nnnnn {⟨normal⟩} {⟨space⟩} {⟨group⟩} {⟨final⟩} {⟨status⟩} {⟨output⟩}
\etl_act:nnnnn ⋆ {⟨token list⟩}

This will add ⟨token list⟩ to the output of \etl_act:nnnnnn. The normal version will add ⟨token list⟩ after the current output, the pre variant will put it before the current output. Might be used inside of the ⟨normal⟩, ⟨space⟩, or ⟨group⟩ code of \etl_act:nnnnnn.

\footnote{Thanks to Bruno Le Floch for pointing that out.}
After this macro was used all remaining things inside the \(\langle \text{token list} \rangle\) argument of \etl_act:nnnnnn will be added to the output. The normal version will add it to the end of the output, the pre variant will put the remainder before the current output in reversed order. Might be used inside of the \(\langle \text{normal} \rangle\), \(\langle \text{space} \rangle\), or \(\langle \text{group} \rangle\) code of \etl_act:nnnnnn.

This will change the current status of \etl_act:nnnnnn to \(\langle \text{status} \rangle\). Might be used inside of the \(\langle \text{normal} \rangle\), \(\langle \text{space} \rangle\), or \(\langle \text{group} \rangle\) code of \etl_act:nnnnnn.

You can put \(\langle \text{token list} \rangle\) back into the input stream to be reconsidered by the current \etl_act:nnnnnn loop (of course this doesn’t have to be literally put back, you might add completely new contents with this). Might be used inside of the \(\langle \text{normal} \rangle\), \(\langle \text{space} \rangle\), or \(\langle \text{group} \rangle\) code of \etl_act:nnnnnn.

With these functions you can change the provided code to act on \(\langle \text{normal} \rangle\) (so N-type) tokens, \(\langle \text{space} \rangle\)s, and \(\langle \text{group} \rangle\)s. Might be used inside of the \(\langle \text{normal} \rangle\), \(\langle \text{space} \rangle\), or \(\langle \text{group} \rangle\) code of \etl_act:nnnnnn.

This will immediately stop the current \etl_act:nnnnnn invocation and execute the provided \(\langle \text{final} \rangle\) code (or if a variant without the \(\langle \text{final} \rangle\) code was used, the output). The \(\langle \text{final} \rangle\) code will receive the current status followed by the current output as two arguments (just like it would when the end of the \(\langle \text{token list} \rangle\) was reached). Might be used inside of the \(\langle \text{normal} \rangle\), \(\langle \text{space} \rangle\), or \(\langle \text{group} \rangle\) code of \etl_act:nnnnnn.

This will immediately stop the current \etl_act:nnnnnn invocation and leave the current output in the input stream. The discard variant will gobble the current output and leave nothing in the input stream. Might be used inside of the \(\langle \text{normal} \rangle\), \(\langle \text{space} \rangle\), or \(\langle \text{group} \rangle\) code of \etl_act:nnnnnn.

This will immediately stop the current \etl_act:nnnnnn invocation, gobble the current output and leave \(\langle \text{token list} \rangle\) in the input stream. Might be used inside of the \(\langle \text{normal} \rangle\), \(\langle \text{space} \rangle\), or \(\langle \text{group} \rangle\) code of \etl_act:nnnnnn.
1.2 Conditionals

\etl_token_if_eq_p:NN \etl_token_if_eq_p:NN ⟨token1⟩ ⟨token2⟩
\etl_token_if_eq:NN ⟨token1⟩ ⟨token2⟩ {⟨true code⟩} {⟨false code⟩}

Compares ⟨token1⟩ and ⟨token2⟩ and yields true if the two are equal. Two tokens are considered equal if they have the same meaning (so if \if_meaning:w is true) and the same string representation (so if \str_if_eq:nnTF is true).

\etl_token_if_eq_p:NN ⋆ \etl_token_if_eq:NN ⋆
\etl_token_if_eq_p:NN \etl_token_if_eq:NN ⋆

Compares ⟨token list1⟩ and ⟨token list2⟩ by comparing them token-by-token. Keep in mind that there are tokens which can't be told apart from each other, and that groups are normalised. If both token lists match (modulo the mentioned limitations) the ⟨true code⟩ is left in the input stream, else the ⟨false code⟩.

\etl_token_if_in_p:nN \etl_token_if_in:nN ⋆ \etl_token_if_in_p:nN ⋆
\etl_token_if_in:nN \etl_token_if_in:nN ⋆

Searches for ⟨token⟩ inside the ⟨token list⟩. If it is found returns true. Brace groups inside the ⟨token list⟩ are ignored.

\etl_token_if_in_deep_p:nN \etl_token_if_in_deep:nN ⋆ \etl_token_if_in_deep_p:nN ⋆
\etl_token_if_in_deep:nN \etl_token_if_in_deep:nN ⋆

Searches for ⟨token⟩ inside the ⟨token list⟩. If it is found returns true. Brace groups inside the ⟨token list⟩ are recursively searched as well.

\etl_token_if_in_p:nN \etl_token_if_in:nN ⋆ \etl_token_if_in_p:nN ⋆
\etl_token_if_in:nN \etl_token_if_in:nN ⋆

Searches for ⟨search text⟩ inside of ⟨token list⟩. If it is found the ⟨true code⟩ is left in the input stream, else the ⟨false code⟩. Both macro parameter tokens as well as tokens with category code 1 and 2 (normally {}) can be part of ⟨search text⟩ (unlike for the similar function \tl_if_in:nnTF). Material inside of groups in ⟨token list⟩ is ignored (except for the groups contained in ⟨search text⟩). So the following would first yield true and then false:

\etl_if_in:nnTF { a(b(c)) } { b(c) } { true } { false }
\etl_if_in:nnTF { a(b(c)) } { b(c) } { true } { false }

\etl_token_if_in_deep_p:nN \etl_token_if_in_deep:nN ⋆ \etl_token_if_in_deep_p:nN ⋆
\etl_token_if_in_deep:nN \etl_token_if_in_deep:nN ⋆

Does the same as \etl_token_if_in:nnTF but also recursively searches inside of groups in ⟨token list⟩. So this would yield true in both of the cases in above example.
1.3 Modifying token lists

\etl_token_replace_once:nNn \etl_token_replace_once:nNn \{\mbox{token list}\} \{\mbox{token}\} \{\mbox{replacement}\}

This function will replace the first occurrence of \mbox{token} inside of \mbox{token list} that is not hidden inside a group with \mbox{replacement}. The \mbox{token} has to be a valid \texttt{N}-type argument.

\TeXhackers note: The result is returned within \texttt{\exp_not:n}, which means that the token list does not expand further when appearing in an \texttt{x-} or \texttt{e-type} argument expansion. The result will be returned after exactly two steps of expansion.

\etl_token_replace_all:nNn \etl_token_replace_all:nNn \{\mbox{token list}\} \{\mbox{token}\} \{\mbox{replacement}\}

This function will replace each occurrence of \mbox{token} inside of \mbox{token list} that is not hidden inside a group with \mbox{replacement}. The \mbox{token} has to be a valid \texttt{N}-type argument.

\TeXhackers note: The result is returned within \texttt{\exp_not:n}, which means that the token list does not expand further when appearing in an \texttt{x-} or \texttt{e-type} argument expansion. The result will be returned after exactly two steps of expansion.

\etl_token_replace_all_deep:nNn \etl_token_replace_all_deep:nNn \{\mbox{token list}\} \{\mbox{token}\} \{\mbox{replacement}\}

This function will replace each occurrence of \mbox{token} inside of \mbox{token list} with \mbox{replacement}. The \mbox{token} has to be a valid \texttt{N}-type argument.

\TeXhackers note: The result is returned within \texttt{\exp_not:n}, which means that the token list does not expand further when appearing in an \texttt{x-} or \texttt{e-type} argument expansion. The result will be returned after exactly two steps of expansion.

\etl_replace_once:nnn \etl_replace_once:nnn \{\mbox{token list}\} \{\mbox{search text}\} \{\mbox{replacement}\}

This function will replace the first occurrence of \mbox{search text} inside of \mbox{token list} that is not hidden inside a group with \mbox{replacement}.

\TeXhackers note: The result is returned within \texttt{\exp_not:n}, which means that the token list does not expand further when appearing in an \texttt{x-} or \texttt{e-type} argument expansion. The result will be returned after exactly two steps of expansion.

\etl_replace_all:nnn \etl_replace_all:nnn \{\mbox{token list}\} \{\mbox{search text}\} \{\mbox{replacement}\}

This function will replace all occurrences of \mbox{search text} inside of \mbox{token list} that are not hidden inside a group with \mbox{replacement}.

\TeXhackers note: The result is returned within \texttt{\exp_not:n}, which means that the token list does not expand further when appearing in an \texttt{x-} or \texttt{e-type} argument expansion. The result will be returned after exactly two steps of expansion.
\etl_replace_all_deep:nnn \* \etl_replace_all_deep:nnn \{token list\} \{search text\} \{replacement\}

This function will replace all occurrences of \{search text\} inside of \{token list\} with \{replacement\}.

\textbf{TeXhackers note}: The result is returned within \exp_not:n, which means that the token list does not expand further when appearing in an x- or e-type argument expansion. The result will be returned after exactly two steps of expansion.

### 1.4 New expandable functions

Functions generated with the means in this section are roughly as fast as the \l3tl variants of them (there might be performance differences; in any case they are faster than the generic functions above), but have at least one fixed argument. They don't have the drawback of not being able to tell apart an active character from a token with the same character code and different category code if the active character was let to it and they don't normalise braces to \{1 and \}2.

#### 1.4.1 Conditionals

\etl_new_if_in:Nnn \etl_new_if_in:Nnn \{function\} \{search text\} \{conditions\}

This will define a new \{function\} which will act as a conditional and search for \{search text\} inside of an n-type argument completely expandable. The \{conditions\} should be a comma-separated list containing one or more of p, T, F and TF (just like for \prg_new_conditional:Nppnn). The \{search text\} must not contain tokens with category code 1 or 2 (normally {}) and can't contain macro parameter tokens (normally #). Unlike for the conditionals in \textit{subsection 1.2}, the \{search text\} of functions created with \etl_new_if_in:Nnn might contain \s__etl_stop tokens.

So the following would yield true followed by false:

\etl_new_if_in:Nnn \etl_new_if_in:Nnn \my_if_a_in:n \{ a \} \{ TF \}
\my_if_a_in:nTF \{ a text \} \{ true \} \{ false \}
\my_if_a_in:nTF \{ text \} \{ true \} \{ false \}
1.4.2 Modifiers

\etl_new_replace_once:Nn \etl_new_replace_once:Nn (function) \((search\ text)\)
This defines a new (function) that'll accept two arguments (the first being a token list, the second a replacement). The generated (function) will replace the first occurrence of \((search\ text)\) inside the token list with replacement. It'll ignore things hidden inside a group in the token list. Neither the (search\ text) nor the token list given to the generated (function) can contain \s_etl_stop (this would result in undefined behaviour), the given replacement on the other hand might contain that token. Additionally (search\ text) can't contain tokens of category group begin or group end (usually { and }) or macro parameters (usually #).

\textit{\LaTeX}hackers\ note: The result of (function) is returned within \exp_not:n, which means that the token list does not expand further when appearing in an \textit{x-} or \textit{e-type} argument expansion. The result will be returned after exactly two steps of expansion.

So the following would yield AcDC:

\etl_new_replace_once:Nn \my_replace_C_once:nn \{ C \}
\my_replace_C_once:nn \{ ACDC \} \{ c \}

\etl_new_replace_all:Nn \etl_new_replace_all:Nn (function) \((search\ text)\)
This behaves like \etl_new_replace_once:Nn, but the (function) will replace all occurrences of \((search\ text)\) instead of just the first.

\textit{\LaTeX}hackers\ note: The result of (function) is returned within \exp_not:n, which means that the token list does not expand further when appearing in an \textit{x-} or \textit{e-type} argument expansion. The result will be returned after exactly two steps of expansion.

So the following would yield AcDc:

\etl_new_replace_all:Nn \my_replace_C_all:nn \{ C \}
\my_replace_C_all:nn \{ ACDC \} \{ c \}

1.5 Bugs and Feature Requests
If you find bugs or want to request features you can do so either via email (see the first page) or via Github at \url{https://github.com/Skillmon/ltx_etl/issues}. 
2 Implementation

\ProvidesExplPackage{etl} {2021-08-28} {0.2}
{expandable token list manipulation}

Tell who we are:
\ProvidesExplPackage{etl} {2021-08-28} {0.2}
{expandable token list manipulation}

Ensure dependencies are met:
\cs_if_exist:NF \tex_expanded:D
{
{\msg_new:nnn { etl } { expanded-missing } }
{ The~ expanded~ primitive~ is~ required. }
{\msg_fatal:nn { etl } { expanded-missing }
}
}

2.1 Primitives

\_etl\_expanded:w Private copies of a few primitives (evil code for expl3).
\_etl\_unexpanded:w
\_etl\_detokenize:w
\cs_new_eq:NN \_etl\_expanded:w \tex\_expanded:D
\cs_new_eq:NN \_etl\_unexpanded:w \tex\_unexpanded:D
\cs_new_eq:NN \_etl\_detokenize:w \tex\_detokenize:D

(End definition for \_etl\_expanded:w, \_etl\_unexpanded:w, and \_etl\_detokenize:w.)

2.2 Variables

\_s\_etl\_stop Scan marks.
\_s\_etl\_mark
\scan_new:N \_s\_etl\_stop
\scan_new:N \_s\_etl\_mark

(End definition for \_s\_etl\_stop and \_s\_etl\_mark)

2.3 Small auxiliaries

\_etl\_if\_mark:nTF A small check whether some argument contains the scan mark \_s\_etl\_mark, the mark
\_etl\_if\_mark:w should always be the last token of the argument (and only a single such mark should be
\_etl\_if\_mark_true:w contained) to ensure correct behaviour.
\cs_new:Npn \_etl\_if\_mark:nTF \_etl\_if\_mark:w \_etl\_if\_mark_true:w \_s\_etl\_mark \use\_ii:nn }
\cs_new:Npn \_etl\_if\_mark:w \_etl\_if\_mark_true:w \_s\_etl\_mark \use\_ii:nn \#12 \#1}

(End definition for \_etl\_if\_mark:nTF, \_etl\_if\_mark:w, and \_etl\_if\_mark_true:w)

\_etl\_split\_first:w Can be used to extract the first element from a token list, it should always be used like
\exp_after:wN (function) \_etl\_split\_first:w (arg).
\cs_new:Npn \_etl\_split\_first:w \_etl\_split\_first:w \_etl\_split\_first:w \_etl\_split\_first:w \_etl\_split\_first:w
{ \_etl\_unexpanded:w \#1 }
\if_false: { \fi: \exp_after:wN \_etl\_split\_first:w \_etl\_split\_first:w \_etl\_split\_first:w \_etl\_split\_first:w \_etl\_split\_first:w \_etl\_split\_first:w \_etl\_split\_first:w

8
Fast ways to change the outcome of a test.
\[\textbf{26} \text{cs_new:Npn } \_\_\_etl_turn_true:w \text{\texttt{\ if\_false: \{ \texttt{if\_true: \} }}\text{\texttt{\fi: \text{\texttt{\if\_false: \}}}}\text{\texttt{\}}}

Fast macro to gobble an immediately following single space.
\[\text{\texttt{28} use:n \{ \cs_new:Npn \_\_\_etl_rm_space:w \}}\text{\texttt{\}}\text{\texttt{\}}\text{\texttt{\} - \{}\text{\texttt{\}}}

This is a fast test whether something is empty or not. The argument must not contain \texttt{s\_etl\_stop} for this to work (but since that limitation is true for most if not all user-facing functions of this module, this is fine to gain a bit of speed).
\[\text{\texttt{29} cs_new:Npn \_\_\_etl_if_empty:nT #1 \}}\text{\texttt{\}}\text{\texttt{\}}\text{\texttt{\} - \{}\text{\texttt{\}}\text{\texttt{\}} \text{\texttt{\}}}

This test works pretty much the same way \_\_\_etl\_if\_head\_is\_group:nTF works, but it is faster because it gets rid of the unnecessary \texttt{\if:w and instead only works by argument gobbling. Drawback is that if you only expand the macro twice you could end up with unbalanced braces.
\[\text{\texttt{46} cs_new:Npn \_\_\_etl_if_head_is_group:nTF #1 \}}\text{\texttt{\}}\text{\texttt{\}}\text{\texttt{\} - \{}\text{\texttt{\}}\text{\texttt{\}} \text{\texttt{\}}}

(End definition for \_\_\_etl\_split\_first:w.)

(End definition for \_\_\_etl\_turn\_true:w and \_\_\_etl\_fi\_turn\_false:w.)

(End definition for \_\_\_etl\_rm\_space:w.)

(End definition for \_\_\_etl\_if\_empty:nTF)

(End definition for \_\_\_etl\_if\_empty:nT)

(End definition for \_\_\_etl\_if\_empty:w)

(End definition for \_\_\_etl\_if\_empty\_true:w)

(End definition for \_\_\_etl\_if\_empty\_true\_TF:w)

(End definition for \_\_\_etl\_rm\_space:w.)

(End definition for \_\_\_etl\_if\_head\_is\_group:nTF)

(End definition for \_\_\_etl\_if\_head\_is\_group:nT)

9
2.4 The act loop

The act loop is modelled after the expl3 internal \_\_tl_act:NNnn but with a few more features making it more general. Those are (argument to \etl_act:nnnnnn in parentheses): a status (\#5), n-type mapping instead of just N-type functions, a final result processing (\#4), and the possibility to preset some output (\#6). The other arguments are: \#7 the token list on which we should act, \#1 function to use for N-type elements in that list, \#2 function to use for spaces in that list, and \#3 function to use on groups in that list.

Just like the \_\_tl_act:NNnn function, this has a token which must not occur in the arguments, in this case that token is \s__etl_stop. The result is stored as an argument to the (undefined) function \_\_etl_act_result:n.

\cs_new:Npn \etl_act:nnnnnnn #1#2#3#4#5#6#7
\{ \__etl_unexpanded:w \__etl_expanded:w
\{ \__etl_act:w #7 \{\s__etl_stop\} \__etl_stop \{#5\} \{#1\} \{#2\} \{#3\}
\__etl_act_result:n \{#6\} \{#4\}
\}
\}

We also provide a version without the \_\_etl_unexpanded:w around it for internal purposes, in which we'd otherwise have to remove it for correct behaviour.

\cs_new:Npn \_\_etl_act:nnnnnnn #1#2#3#4#5#6#7
\{ \__etl_expanded:w
\{ \__etl_act:w #7 \{\s__etl_stop\} \__etl_stop \{#5\} \{#1\} \{#2\} \{#3\}
\__etl_act_result:n \{#6\} \{#4\}
\}
\}

We also provide two reduced function variants, the first without presetting some output, the second also without the final processor.

\exp_args:Nno \use:n { \cs_new:Npn \etl_act:nnnnn \{#1\} \{#2\} \{#3\} \{#4\} \{\#5\} \{#6\} }
\exp_args:Nno \use:n { \cs_new:Npn \etl_act:nnnn \{#1\} \{#2\} \{#3\} \{#4\} \{\#5\} }
\exp_args:Nno \use:n { \cs_new:Npn \etl_act:nnn \{#1\} \{#2\} \{\#3\} \{#4\} \{\#5\} \{#6\} }

The final processor is provided with two n-type arguments (both in braces) the first being the status, the second the output. To just get the output we gobble the status and put \_\_etl_unexpanded:w there to protect the final output from further expanding.

\cs_new:Npn \_\_etl_act_result:nn #1 \{ \_\_etl_unexpanded:w \}

(End definition for \etl_act:nnnnnnn and others. These functions are documented on page 2.)
We need a few macros with spaces at weird places so define them here. Since we got the limitation of not allowing \s__etl_stop we can use that token to get some fast tests. The first tests for a space at the front, and since that one is pretty fast we can use it to build a faster alternative to check for a starting N-type as well (with the drawback that this would yield true for an empty argument, something we have to keep in mind).

\group_begin:
\cs_set:Npn \__etl_tmp:n #1
{
  \__etl_act_if_space:w

\cs_new:Npn \__etl_act_group:w
{
  \__etl_act:w
  \__etl_act_group:w
  ##3
  {##5}
}
\cs_new:Npn \__etl_act_normal:w
{
  \__etl_act:w
  \__etl_act_group:w
  ##3
  {##4}
}
\cs_new:Npn \__etl_act:w #1 \s__etl_stop #2 #3 #4 #5
{
  \__etl_act_if_space:w
  \s__etl_stop \__etl_act_group:w {##4}
  \s__etl_stop \__etl_act_group:w
  \__etl_act_normal:w {##3} {##5}
  {##2}
}
The act loop \__etl_act:w grabs the remainder of the list, delimited by \s__etl_stop, picks up the status (#2), and the user provided functions for N-types (#3), spaces (#4), and groups (#5). We need to check which type is at the head of the token list (the space test is a bit stripped down, and very fast this way).

The check for spaces just gobbles everything up to the first \s__etl_stop. If we found a space at the head we remove that space and leave in the input the space function, the status, and \__etl_act:w for the next iteration.

The act loop \__etl_act:w grabs the remainder of the list, delimited by \s__etl_stop, picks up the status (#2), and the user provided functions for N-types (#3), spaces (#4), and groups (#5). We need to check which type is at the head of the token list (the space test is a bit stripped down, and very fast this way).

The check for spaces just gobbles everything up to the first \s__etl_stop. If we found a space at the head we remove that space and leave in the input the space function, the status, and \__etl_act:w for the next iteration.
\__etl_act_normal:w

For a normal token we can act quite easy, just pick up that token and leave the next iteration in the input stream (#2 is the group code, which is gobbled).

\cs_new:Npn \__etl_act_normal:w #1#2#3#4 { #1 {#3} #4 \__etl_act:w }

(End definition for \__etl_act_normal:w.)

\__etl_act_group:w
\__etl_act_if_end:w

Since the end marker is a single \s__etl_stop in a group, we have to test whether that end marker is found. The test here leads to undefined behaviour if the user supplied token list contains such a marker at any point. If the end marker is found we call the final handler (for which we have to remove the \s__etl_stop to correctly grab its arguments), else we provide the user supplied function the next group and input the next iteration. #1 is the normal function, which is gobbled.

\cs_new:Npn \__etl_act_group:w \__etl_act_normal:w #1#2#3#4
\cs_new:Npn \__etl_act_if_end:w #1 \s__etl_stop {}
\etl_act_status:n\etl_act_put_back:n\etl_act_switch:nnn
\etl_act_switch_normal:n\etl_act_switch_space:n\etl_act_switch_group:n
\etl_act_do_final: \etl_act_break: \etl_act_break_discard: \etl_act_break:n
\etl_act_break_pre:n \etl_act_break_post:n

End definition for \etl_act_output:n and others. These functions are documented on page 2.

\etl_act_status:n  Just switch out the status which is stored immediately after \s__etl_stop.
\etl_act_put_back:n  Place the first argument after the next iteration of the loop. This macro might strip a set of braces around #2, because it could happen that the user provided code only leaves one group between this functions argument and \__etl_act:w, but that would arguably be wrong input anyway, an easy fix would be to use
\etl_act_switch:nnn \etl_act_switch_normal:n \etl_act_switch_space:n \etl_act_switch_group:n  Pretty straight forward, just switch out the user provided functions for the new argument.
\etl_act_do_final: \etl_act_break: \etl_act_break_discard: \etl_act_break:n \etl_act_break_pre:n \etl_act_break_post:n  These are different forms to end the loop. The first will gobble the remainder and apply the final action on the token list currently stored for output.

The break variants will gobble the final action and output what’s currently there (except for the discard variant).
End definition for \etl_act_do_final: and others. These functions are documented on page 3.

#### 2.5 Expandable tests

We consider two tokens equal when they have the same meaning and the same string representation. This isn’t always correct. If an active character is let to the same character with a different category code those two tokens aren’t distinguishable by expansion, *afaik*. To get the optimisation of \prg_new_conditional:Nnnn we use \if_false: and turn it true if both tests are true (this is easier than coding all four variants by hand, even though that could give slightly better performance). The exception being the TF variant, since that is used in the inner loop of many functions. The braces around the arguments of \token_if_eq_meaning:NNT are necessary because of the first step of expansion applied to that function.

Searching for just a single token is rather easy, we just loop over the list and compare the \texttt{N}~type tokens to the one token provided. If we find a match we break and return true, else we’ll return false eventually.
The deep variant just has to recursively call itself on groups to also search those.

\begin{verbatim}
\etl_token_if_in_deep_p:nN
\etl_token_if_in_deep:nTF
\__etl_token_if_in_deep:Nn
\etl_if_eq_p:nn
\etl_if_eq:nn
\__etl_if_eq_normal:nN
\__etl_if_eq_normal:NnN
\__etl_if_eq_space:n
\__etl_if_eq_group:nn
\__etl_if_eq_group:nnn
\__etl_if_eq_final:nn
\end{verbatim}

The test needs to compare the full lists on a token-by-token basis. One of the two lists is stored inside the status the other is processed. The act code will then leave either \texttt{if_false}: or \texttt{if_true}: in the input stream.

\begin{verbatim}
\etl_if_eq_p:nn
\etl_if_eq:nnn
\__etl_if_eq_normal:nN
\__etl_if_eq_normal:NN
\__etl_if_eq_space:n
\__etl_if_eq_group:nn
\__etl_if_eq_group:nnn
\__etl_if_eq_final:nn
\end{verbatim}

To compare the next token we need to check whether the status is already empty (which would mean that token list is longer, hence not equal), if it’s not empty and the head is
N-type we compare these two (the test here for N-type fails for empty arguments, hence we have to test this separately). If they are equal we store the rest of the second token list in the status and go on with the loop, else we break out and return false.

\begin{verbatim}
\exp_args:Nno \use:n { \cs_new:Npn \__etl_if_eq_normal:nN #1#2 }
\exp_args:Nno \use:n { \cs_new:Npn \__etl_if_eq_normal:nN #1#2 #2 }
\exp_args:Nno \use:n { \cs_new:Npn \__etl_if_eq_space:n #1 }
\exp_args:Nno \use:n { \cs_new:Npn \__etl_if_eq_group:nn #1 }
\exp_args:Nno \use:n { \cs_new:Npn \__etl_if_eq_group:nnn #1#2#3 }
\exp_args:Nno \use:n { \cs_new:Npn \__etl_if_eq_final:nn #1#2 }
\end{verbatim}

Spaces are pretty similar, but easier, we don’t need to split of the first token in a complicated manner, instead we just gobble a leading space.

Groups are similarly handled to normal arguments, but instead of comparing only two tokens we have to compare by recursion.

Finally, if the loop didn’t break until the first token list is empty we just have to make sure that the second list is also empty by now. If that’s the case the two are equal, else not. We need to leave either true or false (protected against the \_etl\_expanded:w expansion) in the input.

\begin{verbatim}
\exp_args:Nno \use:n { \cs_new:Npn \__etl_if_eq_final:nn #1#2 }
\end{verbatim}
\etl_if_in:nn has to reevaluate every token but the very first in order to compare them, else something like ab wouldn’t contain ab according to the test, because the second would’ve been gobbled. For this we need \etl_if_in_put_back:n which will remove the first token (we need to watch out for spaces) and puts the rest back using \etl_act_put_back:n.

\exp_after:wN \etl_unexpanded:w
\__etl_if_empty:nT (#1) { \{ \if_true: \} \use_none:n } { \if_false: }
\)

(End definition for \etl_if_eq:nnTF and others. This function is documented on page 4.)

\etl_if_in:nn has to reevaluate every token but the very first in order to compare them, else something like aab wouldn’t contain ab according to the test, because the second would’ve been gobbled. For this we need \etl_if_in_put_back:n which will remove the first token (we need to watch out for spaces) and puts the rest back using \etl_act_put_back:n.

\exp_after:wN \etl_unexpanded:w
\__etl_if_empty:nT (#1) { \{ \if_true: \} \use_none:n } { \if_false: }
\)

As already said, we’ll need to reinsert some tokens, and we’ll might have to revert what was already matched, so instead of the state we store the remainder of the pattern which needs to be matched, followed by the entire pattern, followed by the tokens which were already matched (and might need to be put back). As soon as the pattern is matched the remainder will be empty and we’ll leave \if_true: in the input, at the end of the entire list we’ll leave \if_false:, which we store in the prefilled output. The emptiness of the pattern will be checked before the next token is evaluated, so the trailing space after #1 does no harm but allows the token list to end in the pattern.

All of the macros used as arguments to \etl_act:nnnnnnn will need to unbrace the status which will then lead to three arguments. Else this is pretty much the same idea as \etl_if_eq:nnTF.

\exp_after:wN \etl_unexpanded:w
\__etl_if_empty:nT (#1) { \{ \if_true: \} \use_none:n } { \if_false: }
\)

Just like \etl_if_in_group:nn, \etl_if_in_normal:nN needs to split off the first token of the pattern, for which \etl_split_first:w is used, and \etl_if_in_space:n needs to trim off a leading space.

\cs_new:Npn \etl_if_in_normal:nN #1 \#2 { #2 } \if_true: \}
\else: \prg_return_false: \fi: \etl_if_head_is_N_type:nTF {#1} \}
\}
\end{verbatim}

\begin{verbatim}
\cs_new:Npn \__etl_if_in_normal:nN #1 { \__etl_split_first:w { #1 } { \etl_if_in_normal:nN \etl_if_in_space:n \etl_if_in_group:nn \etl_act:nnnnnnn } \__etl_if_head_is_space:nTF {#1} \}
\__etl_if_empty:nT (#1) { \etl_act_break:n \if_true: }
\__etl_if_head_is_N_type:nTF (#1) \}
\end{verbatim}

17
In essence this is the same as \texttt{etl\_if\_in:nnTF}, but additionally every time a group is encountered we need to search that group by recursion as well after directly comparing it to the pattern.

\[\text{\texttt{etl\_if\_in:nnTF}}\]

\[\text{\texttt{etl\_if\_in:nn}}\]

\[\text{\texttt{etl\_if\_in\_group:nn}}\]

\[\text{\texttt{etl\_if\_in\_deep:nn}}\]

\[\text{\texttt{etl\_if\_in\_deep\_false:nn}}\]
2.6 Expandably modify token lists

Replacing a single token (and in fact the same is true for all the replacement actions in this package) doesn’t need reordering and no post-processing, so we can use in place output using \__etl_unexpanded:w. We store the token we want to replace inside the act function, as well as an additional argument which will be executed once a replacement was done (this is used for the \etl_token_replace_once:nNn function).

\exp_args:Nno \use:n \cs_new:Npn \etl_token_replace_all:nNn #1#2#3
\etl_act:nnnnnn
\__etl_token_replace:NnnN #2 {}
\__etl_act_unexpanded_space:n
\__etl_act_unexpanded_group:nn
\use_none:nn
#{3}
#{1}
\exp_args:Nno \use:n \cs_new:Npn \__etl_token_replace:NnnN #1#2#3#4
\etl_token_if_eq:NNTF {#1} {#4}{ \__etl_unexpanded:w {#3} #2 }{ \__etl_unexpanded:w {#4} }

(End definition for \etl_token_replace_all:nNn and \__etl_token_replace:NnnN. This function is documented on page 5.)

\etl_token_replace_all_deep:nNn
\__etl_token_replace_deep:Nnn
Deep replacement is done by recursion. Since the deep variant will not execute any additional code we omit such an additional argument for it.

\exp_args:Nno \use:n \cs_new:Npn \etl_token_replace_all_deep:nNn #1#2#3
\etl_act:nnnnnn
\__etl_token_replace:NnnN #2 {}
\__etl_token_replace_deep:Nnn #2
\use_none:nn
#{3}
#{1}

Here #{1} is used to get correct results from the first step of expansion done directly.

\exp_args:Nno \use:n \cs_new:Npn \__etl_token_replace_deep:Nnn #1#2#3
\exp_after:wN \etl_token_replace_all_deep:nNn {#3} {#{1} {#2} }

(End definition for \etl_token_replace_all_deep:nNn and \__etl_token_replace_deep:Nnn. This function is documented on page 5.)

\etl_token_replace_once:nNn
To only handle the first matching token we just let the replacement internal exchange the function to directly output any token.

\exp_args:Nno \use:n \cs_new:Npn \etl_token_replace_once:nNn #1#2#3
\etl_act:nnnnnn
\__etl_token_replace:NnnN #2
{ \etl_act_switch_normal:n \__etl_act_unexpanded_normal:nN }
Replacing an arbitrary number of tokens (which might include braces and spaces) is quite a bit harder than a single \texttt{N}-type. We place in the status the remainder of the pattern, the full pattern, delayed tokens (those which matched the pattern), the replacement, and a marker which should tell us whether we want to only replace the first match (if so use \texttt{\use:nn}, else any other single token).

\begin{verbatim}
\exp_args:Nno \use:n \cs_new:Npn \etl_replace_all:nnn #1#2#3 
{ \etl_act:nnnnnn \etl_act_put_back:n \etl_act_put_back_normal:Nn \etl_act_put_back_group:nn \etl_act_put_back_final:nn \etl_act_status:n { {#2} {#2} {} {#3} \scan_stop: } }\end{verbatim}

We again need to be able to put back a few tokens, but this time we also need to know whether the first token is an \texttt{N}-type or group, because we can't just gobble the first element but need to output it unchanged.

\begin{verbatim}
\exp_args:Nno \use:n \cs_new:Npn \etl_replace_put_back:nnnN #1#2#3#4 
{ \etl_if_head_is_space:nTF {#1} 
{ \etl_act_put_back:n \etl_act_put_back:n \etl_act_put_back:nnnN #1#2#3#4 } \etl_if_head_is_group:nTF {#1} 
{ \etl_act_put_back:n \etl_act_put_back_normal:nn } \etl_act_status:n { {#3} {#3} {#3} {#3} }\end{verbatim}
Just to keep track of the different arguments here: \#1 is the next token in the pattern, \#2 is the remainder of the pattern, \#3 is the full pattern stored for reuse, \#4 are the delayed tokens, which might need to be put back, \#5 is the replacement text, \#6 is the marker which might indicate the once function, and \#7 is the next token of the input.
And again, \#1 the next group of the pattern, \#2 the remainder of the pattern, \#3 the full pattern, \#4 the delayed stuff, \#5 the replacement text, \#6 the marker for the once function, \#7 the next group in the input.
The deep variant works again pretty much the same as the all variant, except that it searches groups recursively.

```latex
\begin{verbatim}
\cs_new:Npn \__etl_replace_group_deep:nnn 
\__etl_replace_normal:nN 
\__etl_replace_space:n 
\__etl_replace_group_deep:nn 
\__etl_replace_final:nn
\__etl_replace_put_back:nnnN
\exp_args:Nno \use:n { \cs_new:Npn \etl_replace_all_deep:nnn #1#2#3 }
\etl_act:nnnnnn
\__etl_replace_normal:n 
\__etl_replace_space:n 
\__etl_replace_group_deep:nn 
\__etl_replace_final:nn
\__etl_replace_put_back:nnnN}
\cs_new:Npn \__etl_replace_group_deep:nnn #1
\__etl_if_head_is_group:nTF {#1}
\exp_after:wN \__etl_replace_group_deep:nnnnNn
\__etl_split_first:w #1
\__etl_expanded:w { \__etl_split_first:w #1 }
\__etl_replace_put_back:nnnN { #4 {#7} } {#3} {#5} #6
\__etl_replace_put_back:nnnN
\exp_args:Nno \use:n { \cs_new:Npn \__etl_replace_group_deep_false:nnnNn #1#2#3#4#5 }
\__etl_if_empty:nTF {#2}
\__etl_replace_all_deep:nnn (#7) (#3) (5) #6
\__etl_replace_put_back:nnnN ( #4 {#7} ) {#3} (#5) #6
\__etl_replace_put_back:nnnN 
\__etl_replace_all_deep:nnn (#7) (#3) (#5)
\__etl_replace_put_back:nnnN
\__etl_if_head_is_group:nTF {#1}
\exp_after:wN \__etl_replace_group_deep:nnnnNn
\__etl_split_first:w #1
\__etl_expanded:w { \__etl_split_first:w #1 }
\__etl_replace_put_back:nnnN
\exp_args:Nno \use:n { \cs_new:Npn \__etl_replace_group_deep_false:nnnNn #1#2#3#4#5#6#7 }
\__etl_if_empty:nTF {#2}
\__etl_replace_all_deep:nnn (#7) (#3) (#5) #6
\__etl_replace_put_back:nnnN
\exp_args:Nno \use:n { \cs_new:Npn \__etl_replace_group_deep_false:nnnNn #1#2#3#4#5#6#7 }
\__etl_if_empty:nTF {#2}
\__etl_replace_all_deep:nnn (#5) (#1) (#3)
\end{verbatim}
\end{quote}

(End definition for \etl_replace_all:nnn and others. This function is documented on page 5.)
2. Defining new tests

These tests work essentially in the same way as `\tl_if_in:nTF`, but instead they use a predefined internal macro so that no definition at use time is necessary. We use a small loop to get a unique auxiliary macro name for the search text.

```latex
\etl_new_if_in:Nnn
\etl_new_if_in:NnNnn
\etl_new_if_in:NNnn
```

(End definition for `\etl_replace_once:nnn` and others. This function is documented on page 6.)
2.8 Defining new modifiers

The implementation of replace_once and replace_all is modelled closely on the implementation used in \texttt{l3tl}. The difference is that we use a hard coded delimiter (\texttt{\s__etl_stop}) instead of searching for one that is always legal (we can’t do redefinitions, so can’t change the delimiter later based on the token list input).

We need another loop to guarantee unique names, if everything’s alright we go on and define the user function using \texttt{#1} of \texttt{\_\_etl_new_replace_def:NnNn}. An empty search pattern is forbidden and should throw an error.

\begin{verbatim}
\cs_new_protected:Npn \_\_etl_new_replace_def:NnNn #1#2#3#4
\{
  \cs_gset:Npn #1 ##1 #3 {}
  \prg_new_conditional:Npnn #2 ##1 {#4}
  \{
    \if:w
      \scan_stop:
      \__etl_detokenize:w \exp_after:wN { #1 ##1 {} {} #3 }
    \scan_stop:
    \__etl-fi-turn-false:w
    \fi:
    \if_true:
      \prg_return_true:
    \else:
      \prg_return_false:
    \fi:
  \}
\}
\cs_new_protected:Npn \__etl_new_replace_def_aux:NnNnN #1#2#3#4#5
\{
  \tl_if_empty:nTF {#3}
  \{
    \msg_error:nnn { etl } { empty-search-text } { #2 } \}
  \{
    \scan_stop:
    \if_false: {
      \exp_args:Nc \__etl_new_replace_def_aux:NnNnN
      \__etl_user_function - replace - \tl_to_str:n {#3} - :Nw }
    \}
  \}
\}
\cs_new_protected:Npn \_\_etl_new_replace_def_aux:Nn \_\_etl_new_replace_def_aux:Nn
\end{verbatim}
The auxiliary macro uses a loop for the replacement. This is also used for the once variant. This saves internal functions if both an all and a once function are generated for the same search text (though the once variant could be coded easier and faster otherwise, but the performance hit should be small).

We need a few auxiliaries for the two replacement variants here. The first just grabs the already processed part of the token list and protects it from further expanding. The second breaks the loop for the once variant by protecting the remainder of the token list from further expanding. The last just gobbles the remainder of the loop by using an unbalanced brace trick.

The once variant will use \_etl_new_replace_done_once:w if the replacement is successful (that will remove the remainder of the loop, and protect both the replacement and the rest of the token list on which we work from further expanding).
\etl_new_replace_all:Nn \
\_etl_new_replace_all:NNn

The all variant will directly protect the replacement from further expanding and reiterate (due to the way the auxiliary is defined) until the replacement isn’t found anymore.

(End definition for \etl_new_replace_all:Nn and \_etl_new_replace_all:NNn. This function is documented on page 7.)
